# 1 Introduction

## Overview

- 1.1 Broad Energy (Wales) intends to submit a planning application to Welsh Ministers for an Energy Recovery Facility (abbreviated to 'ERF' in this document) and ancillary infrastructure to be located at Buttington Quarry, Buttington, Welshpool, Powys, SY21 8SZ (the Site). A location plan is provided in Section 9 (Figure 1).
- 1.2 BSG Ecology was appointed by Environmental Compliance Limited on 31 May 2018 to undertake an ecological impact assessment for the proposed development, the results of which are presented in the Environmental Statement for the development (ECL, 2020). This assessment revealed that there are two Special Areas of Conservation (SACs) within 10 km of the likely location of the flue gas discharge stack at the Site. These are the Montgomery Canal SAC and Granllyn SAC, which are approximately 1.8 km and 4.3 km from the proposed stack respectively. In addition, Midland Meres and Mosses – Phase 1 Ramsar site is approximately 7.4 km from the proposed stack.
- 1.3 This document presents the results of a shadow Habitat Regulations Assessment<sup>1</sup>, which will provide information that will help Welsh Ministers to discharge their duties as the 'competent authority' as defined under Regulation 63(1) of the Conservation of Habitats and Species Regulations 2017 (hereafter referred to as the 'Habitats Regulations').

## Site description

- 1.4 The development area in the floor of the quarry is mainly bare ground. Scattered short-lived annual and ruderal plant species are present around the fringes of the quarry, and reedmace *Typha latifolia* occurs in the pools that are present. The access track to the development area is also bare ground (compacted quarried material).
- 1.5 Within the southern part of the Site there is a network of tracks through remnant areas of semi-improved neutral grassland (pasture), ruderal habitats and scattered scrub. Fragments of hedgerows are present, but these are not linked to a wider hedgerow network due to a network of tracks and areas of former quarrying activity which have resulted in habitat fragmentation.
- 1.6 Woodland is present to the north-west of the Site (a small area extends into the Site but is outside the development footprint). The nearer areas of woodland to the development site are dominated by conifers, with semi-natural broadleaved woodland further to the west. The woodland is a mixture of plantation on an ancient woodland site and restored ancient woodland.
- 1.7 A strong linear habitat feature extends along the line of a dismantled railway between the woodland and the A453 approximately 2.5 km to the north; it is dominated by scrub and developing woodland and is likely to provide a commuting / dispersal corridor through the area for various species. Otherwise, the landscape around the site is dominated by mixed farmland.

## The proposed works

- 1.8 It is proposed to construct and operate a plant capable of generating around 12.8MWe of low carbon and renewable energy through the thermal treatment of up to 167,000 tonnes per annum of residual wastes sourced from Powys and surrounding areas as a feedstock. Such feedstock would be derived from municipal, industrial and commercial sources and would consist of material having passed through recovery centres for reuse and recycling and so deemed to have no further use.
- 1.9 The ERF would be capable of generating both electrical and heat energy from the process and so would be classed as a Combined Heat and Power plant (CHP plant).

---

<sup>1</sup> Under the Conservation of Habitats and Species Regulations 2017 the 'competent authority' is responsible for completing a Habitats Regulations Assessment (HRA). The applicant is required under Regulation 63(2) to provide the competent authority with such information as the competent authority may reasonably require to discharge its duties. This report is provided for that purpose. Where a HRA is carried out by an applicant with the objective of it being adopted by the competent authority, this is often referred to as a shadow HRA.

- 1.10 The ERF will use proven, highly regulated technology provided by HZI. Through the combustion of residual waste, it will generate energy in the form of steam to drive a turbine to generate electricity.
- 1.11 The proposed development will include the following elements:
- waste reception area including tipping hall;
  - storage bunker;
  - waste feed hopper;
  - combustion line;
  - boiler and water steam cycle;
  - flue gas treatment;
  - a single stack – 70m in height;
  - bottom ash extraction and storage;
  - steam turbine and generator;
  - electrical transformers;
  - air cooled condensers;
  - and associated utilities infrastructure.
- 1.12 It is anticipated that, following the grant of planning permission, construction would last for approximately 36 months, which includes a 2-3 month commissioning period.

### **Consultation**

- 1.13 In its EIA Scoping Direction dated 3 October 2018, The Planning Inspectorate advised that *'It is noted that the Applicant intends to submit a Habitats Regulations Report (HRA) in order to address the requirements of the Conservation of Habitats and Species Regulations 2017' and 'The Conservation of Habitats and Species Regulations 2017 require competent authorities, before granting consent for a plan or project, to carry out an appropriate assessment (AA) in circumstances where the plan or project is likely to have a significant effect on a European site (either alone or in combination with other plans or projects).'*
- 1.14 It is also noted that *'When considering whether or not significant effects are likely, applicants should ensure that their rationale is consistent with the CJEU finding that mitigation measures (referred to in the judgment as measures which are intended to avoid or reduce effects) should be assessed within the framework of an AA and that it is not permissible to take account of measures intended to avoid or reduce the harmful effects of the plan or project on a European site when determining whether an AA is required'.*
- 1.15 The requirement to undertake a Habitats Regulations Assessment is described in Section 2.

## 2 Habitats Regulations Assessment

### Legislation

- 2.1 The Conservation of Habitats and Species Regulations 2017 (the 'Habitats Regulations') transpose the requirements of two European Directives in to UK legislation:
- i. Council Directive on the conservation of natural habitats and of wild fauna and flora of 21st May 1992 (92/43/EEC) (the 'Habitats Directive'); and
  - ii. Council Directive on the conservation of wild birds of 2nd April 1979 (70/409/EEC) consolidated by Council Directive on the conservation of wild birds 2009 (2009/147/EC (the 'Birds Directive').
- 2.2 The Habitats Directive aims to protect plants, habitats and animals other than birds, and this is achieved in part through the creation of Special Areas of Conservation (SACs).
- 2.3 The Birds Directive aims to protect rare and vulnerable birds and the habitats that they depend upon and this is achieved in part through the classification of Special Protection Areas (SPAs).
- 2.4 The measures in the Directives required to protect these sites are transposed in to UK legislation as the assessment process set out in the Habitats Regulations (see below).
- 2.5 The UK is also a contracting party to the Convention on wetlands of international importance especially as waterfowl habitat, Ramsar, Iran, 1971 (the 'Ramsar Convention') which seeks to protect wetlands of international importance, especially those wetlands utilised as waterfowl habitat. It is UK Government policy (in Wales this is identified in paragraph 6.4.18 of Planning Policy Wales, 2018) that all competent authorities should treat Ramsar sites in their decision making processes as if they are SACs or SPAs. This policy also brings candidate SACs (cSACs) and potential SPAs (pSPAs) within the requirement for HRA.
- 2.6 In this report the term 'European Sites' is used to refer collectively to SACs, SPAs and Ramsar sites.

### Habitats Regulations Assessment process

- 2.7 The requirements of the Habitats Regulations with regard to the implications of plans or projects are set out within Regulation 63. The step-based approach implicit within this regulation is referred to as a 'Habitats Regulations Assessment', which is the term that has been used throughout this report.
- 2.8 It is a requirement of any public body (referred to as a competent authority within the Habitats Regulations) to carry out a Habitats Regulations Assessment when they are proposing to carry out a project, implement a plan or authorise another party to carry out a plan or project. Competent authorities are required to record the process undertaken, ensuring that there will be no adverse effects on the integrity of any European Site as a result of a plan or project whether alone or in combination with other plans or projects.

### Assessment stages

- 2.9 The assessment of a plan or project goes through a number of stages, with guidance having been published to aid competent authorities fulfil their responsibilities (e.g. European Commission 2001; DCLG, 2006). Those stages are summarised in Table 1 below.

**Table 1: Stages in the Habitats Regulations Assessment process**

Stage	Description	Legislative Context
Purpose	Determines if the purpose of the plan or project is directly connected with, or necessary, to the management of a European Site. If it is, then no further assessment is necessary	Regulation 63(1)(b)

Stage	Description	Legislative Context
Scoping	The identification of any European Site that might be within scope of a HRA, i.e. those European Sites should be taken forward to the screening stage based on a wide consideration of spatial and ecological factors. Such European Sites may be located within the plan or project area but may also include sites located in neighbouring authority areas.	
Screening	<p>Assessment of whether a plan or project, either alone or in combination with other plans or projects, is likely to have a significant effect on any European Sites' qualifying features (habitats and species) and the achievement of the European Site's conservation objectives.</p> <p>This is also known as the 'test of likely significant effect' (ToLSE). If significant effects can be ruled out at the screening stage (with no reasonable scientific doubt remaining) then there is no requirement to proceed to the next "Appropriate Assessment" stage or subsequent stages</p>	Regulation 63(1)(a)
Appropriate Assessment	<p>Consideration of the impacts of the proposals to determine whether or not it is possible to conclude with certainty that the development will not result in any adverse effect on the integrity of any European Site, either alone or in combination with other plans or projects and with reference to the European Site's conservation objectives.</p> <p>This is also known as the test of 'adverse effect on integrity' (AEol).</p> <p>At this stage consent may be granted for the plan or project if it is possible to conclude with certainty that the proposal will not result in any adverse effect on the integrity of any European Site, either alone or in combination with other plans or projects.</p>	Regulation 63(5)
If it cannot be concluded with certainty that the proposal will not result in any adverse effect on the integrity of any European Site then proceed to:		
Assessment of alternative solutions	<p>Assess whether there is an alternative solution to the plan or project, i.e. one that better respects European Sites whilst achieving the primary objective of the plan or project.</p> <p>If no such alternative solution exists, the process continues to an assessment of whether there are 'imperative reasons of overriding public interest' (IROPI) for the plan or project to proceed.</p>	Regulation 64(1)
Assessment of IROPI	Assess whether a plan or project can be justified as being needed for 'imperative reasons of overriding public interest' (IROPI).	Regulation 64(1)
Compensatory measures	Identify and secure any necessary compensatory measures to ensure that the overall coherence of the European Site network is protected.	Regulation 68

### Case law on the HRA process

- 2.10 The Court of Justice of the European Union (CJEU) and UK Court judgments have identified that in the HRA process the assessment may not have lacunae (gaps or omissions) and must contain complete, precise and definitive findings capable of removing all reasonable scientific doubt as to the effects of the proposed works on the European Site concerned. Court judgments have identified that in the HRA process all aspects of the plan or project which can, by themselves or in combination with other plans or projects, affect the conservation objectives of European Sites concerned must be identified in the light of the best scientific knowledge available in the field.
- 2.11 A recent CJEU judgment (People Over Wind and Sweetman, 12 April 2018, C-323/17) has provided clarification as to when avoidance or reduction (i.e. mitigation) measures can be considered within the HRA process. The headline for the case is:
- “In the light of all the foregoing considerations, the answer to the question referred is that Article 6(3) of the Habitats Directive must be interpreted as meaning that, in order to determine whether it is necessary to carry out, subsequently, an appropriate assessment of the implications, for a site concerned, of a plan or project, it is not appropriate, at the screening stage, to take account of the measures intended to avoid or reduce the harmful effects of the plan or project on that site”.*
- 2.12 This case means that a competent authority cannot rely on avoidance or reduction measures at the screening stage that allow a conclusion of ‘no likely significant effect’ to be reached: instead it is necessary to accept that there is a ‘likely significant effect’ in the absence of these measures, and move to the next stage, i.e. appropriate assessment, at which point such mitigation measures can be considered. This recent judgment is accounted for in this report.
- 2.13 A further CJEU judgment (Holohan & Ors. v An Bord Pleanála, 7 November 2018, C - 461/17) provides further clarification about the HRA process, requiring that all habitats and species associated with a European Site (irrespective of whether or not they are qualifying features) must be considered in the assessment of impacts on those non-qualifying habitats or species are liable to affect the conservation objectives of the European Site through, for instance, effects on ecological processes or food chains. This recent judgment is also accounted for in this report.

### 3 Scope of the Assessment

- 3.1 The Zone of Influence (Zol) for the proposed development is the area over which ecological features may be affected by biophysical changes as a result of the proposed project and associated activities. This may extend beyond the Site boundary. The Zol has been used to determine the extent of the desk study and baseline ecological surveys.
- 3.2 During the construction stage of the Development the Zol is considered to be the area around the Site where impacts might arise during the construction, operation and decommissioning phases of the development. The extent of the Zol necessarily varies depending upon the sensitivity of the ecological receptors being considered and the impact mechanism being considered. In this assessment the following Zols have been adopted:
- Habitat loss and disturbance will be limited to the Site itself, with dust related impacts potentially extending to 50 m beyond the Site boundary (see below). Excavations and ruts caused by vehicles may have hydrological impacts that are wider ranging, but such impacts are unlikely to extend as far as the nearest European site (the Montgomery Canal is 1.8 km away).
  - Disturbance related impacts on mobile species, such as birds, are potentially wider ranging. Nevertheless, disturbance related impacts on birds are unlikely to extend as far as the nearest European site where the qualifying features includes species that may be vulnerable to disturbance, i.e. the Midland Meres and Mosses - Phase 1 Ramsar, which is 7.4 km away (Ruddock & Whitfield, 2007; Laursen, Kahlert & Frikke, 2005).
  - Airborne pollution has the potential to be dispersed over far greater distances and so for this reason a Zol of 10 km has been adopted based on UK Gov guidance with regard to aerial deposition on sensitive ecological features<sup>2</sup>.
- 3.3 Current guidance (Holman *et al*, 2014) advises that construction related dust impacts only need to be considered for important ecological features within 50 m of the development boundary. As the nearest European site is considerably further away than this, dust arising from the construction and decommissioning phases of the development is not likely to migrate as far as any European site.
- 3.4 Consideration also needs to be given to land that is not subject to a European designation but which may be 'functionally linked' to a European site if it serves a function for the interest features of that site. Functionally linked land has been defined as follows (Chapman & Tyldesley, 2016):
- 3.5 *'the term 'functional linkage' refers to the role or 'function' that land or sea beyond the boundary of a European site might fulfil in terms of ecologically supporting the populations for which the site was designated or classified. Such land is therefore 'linked' to the European site in question because it provides an important role in maintaining or restoring the population of qualifying species at favourable conservation status.'*
- 3.6 In summary, the following potential types of adverse effect have been considered in this assessment:
- Physical habitat loss – land take by the works;
  - Physical habitat damage – from on-site activities;
  - Physical habitat damage – from off-site activities (affecting functionally-linked land);
  - Pollution related impacts – airborne pollution in particular;
  - Disturbance – e.g. noise from working machinery or visible presence of people.
- 3.7 Taking into account these impact mechanisms and the Zols that have been adopted for the assessment, the HRA has only considered impacts on the following European sites:
- Montgomery Canal SAC (1.8 km to the west of the Site);
  - Granllyn SAC (4.3 km to the west of the Site); and

---

<sup>2</sup> <https://www.gov.uk/guidance/air-emissions-risk-assessment-for-your-environmental-permit#steps-to-complete-this-risk-assessment>.

- Midland Meres and Mosses - Phase 1 Ramsar (7.4 km to the south of the Site)

3.8 The locations of these sites relative to the proposed development Site are shown on Figure 2 in Section 9.

3.9 Other than the above sites, the nearest European site is Tanat and Vyrnwy Bat Sites SAC, which is approximately 10.5 km to the north-west of the Site. This site contains a good mixture of lesser horseshoe bat *Rhinolophus hipposideros* maternity and hibernation sites. No impact mechanism has been identified for this European site and so it has been scoped out of this assessment. I.e. the site is in favourable condition. The population of bats using the site could be impacted upon by direct disturbance, deterioration of the external condition or changes in the internal characteristics of the buildings they use, measures to prevent access to the buildings and mines (which provide a complex of hibernation and maternity roost sites) and changes to the surrounding habitats on which the bats rely for foraging. The development of the ERF will not lead to any of these impacts.

## 4 Information on the Relevant European Sites

4.1 Set out below in Tables 2-4 is information relating to the following parameters for each of the European Sites within the scope of the assessment:

- Site name
- Site code
- Year classified/designated/listed
- Area
- Qualifying interest features
- Conservation objectives
- Distance between nearest component of European Site and the proposed development
- Sources of information

4.2 The European Sites that have been considered are the Montgomery Canal SAC, Granllyn SAC and Midland Meres and Mosses – Phase 1 Ramsar site.

Table 2

<b>Site name:</b> Montgomery Canal SAC
Site code: UK0030213
Year designated: 2015
Area: 51.46 ha
<p>Qualifying interest features:</p> <ul style="list-style-type: none"> <li>• Annex II species that are a primary reason for selection of this site: Floating water-plantain <i>Luronium natans</i></li> </ul>
<p>Conservation objectives:</p> <p>The vision is to maintain the extent and distribution of <i>L. natans</i> within the Montgomery Canal at favourable conservation status, where all of the following conditions are satisfied:</p> <ul style="list-style-type: none"> <li>• The <i>L. natans</i> population in favourable condition will reflect the natural carrying capacity of the canal habitat and will be limited principally by species ability to spread or be relocated (vegetative or otherwise), the suitability of the rooting medium and competition between species as part of habitat succession.</li> <li>• Recreation pressure, principally through boat movements and fisheries management, will not significantly affect the maintenance of the species, or its ability to disperse throughout the canal network and any associated off-line reserves.</li> <li>• The ecological status of the water environment, including elements of water quality and physical habitat quality, will be sufficient to support the population of <i>L. natans</i> in favourable condition.</li> <li>• All factors affecting the achievement of the above conditions are under control.</li> </ul>
Distance: The SAC is 1.8 km from the proposed development site.

## Site condition

### **Montgomery Canal SAC**

- 4.3 The condition assessment by Countryside Council for Wales (CCW, now Natural Resources Wales; CCW, 2008) is based on the results of a comprehensive survey completed in 2001. The results of this survey showed that floating water-plantain was widespread along the length of the canal, although there were some lengths where there were no records because of its very low density, recent dredging activity or its local absence. This information led to the conclusion that the population of floating water-plantain was healthy and that this warranted an assessment of favourable condition.
- 4.4 Concerns were raised by CCW, however, about water quality that may account for the current lack of species richness in some parts of the canal. This resulted in the feature being re-assessed as being in unfavourable condition, pending further discussion and investigation with the Environment Agency. It was also noted that some areas of the canal were dominated by *Elodea* spp, which can out-compete the more sensitive species (including *L. natans*).
- 4.5 The Management Plan (CCW, 2008) concluded that (in November 2007) the population of floating water plantain was large and abundant at that time in management units 2 (Vyrnwy Aqueduct to Pentrehelin) and 15 (Red House to Glanhafren).

### **Granllyn SAC**

- 4.6 The condition of the SAC, as demonstrated by the most recent torch survey counts carried out on the site in 2007, was assessed as unfavourable but recovering. During this survey 91 newts were counted in the Granllyn Pool (unit 1) and 5 newts were counted in The Moat (unit 2) water body making 96 in total. The lower limit (target – refer to Conservation Objectives) for the site is 100 individuals. Evidence of egg laying was recorded at this time confirming breeding in Granllyn Pool.
- 4.7 The Core Management Plan (CCW, 2008) reports that the ‘unfavourable recovering’ status was due to the result of pond restoration work at Granllyn Pool in 2005, which fully restored the display/breeding habitat. Whilst this seems like a reasonable analysis, caution needs to be applied to these data as they are now 12 years old.

### **Midland Meres and Mosses – Phase 1 Ramsar site**

- 4.8 There is no specific information available for the Ramsar site; however, condition assessments have been completed for the component SSSIs that collectively make up the Ramsar site (15 in total). Only one component SSSI is present within the 10 km Zol: Marton Pool, Chirbury SSSI.
- 4.9 The condition assessment for Marton Pool, Chirbury SSSI indicates that this site is ‘unfavourable recovering’ due to the past effects of water pollution and agricultural runoff; however, this needs to be treated with caution as the assessment was completed in 2011.

## 5 Identification of any Likely Significant Effects

- 5.1 This section carries out the screening of likely significant effects. This fulfils the requirement of Regulation 63 of the Habitats Regulations that a proposed project is to be assessed to determine whether or not it is likely to have a significant effect on any European Site or any qualifying features (species and habitats) of any European Site, either alone or in combination with other plans or projects.
- 5.2 As part of the screening process it is noted that the proposed development is not directly connected with or necessary to the management of any European Site.
- 5.3 The following European Sites are screened for any likely significant effects:
- Montgomery Canal SAC;
  - Granllyn SAC; and
  - Midland Meres and Mosses – Phase 1 Ramsar site.
- 5.4 The following types of potentially adverse activity are screened as a source of any likely significant effects in accordance with the requirements of Regulation 63 of the Habitats Regulations:
- Changes in air quality resulting in impacts on water quality through deposition.
- 5.5 The following types of potentially adverse activity are screened out as a source of any likely significant effects for the reasons stated:
- Physical habitat loss: The nearest European site is the Montgomery Canal SAC, the nearest part of which is approximately 1.8 km to the west of the Site. The two locations are separated by a road, a railway, farmland and the River Severn, which collectively will buffer the SAC from any direct or indirect impacts on habitats.
  - Physical habitat damage: See above rationale regarding physical habitat loss.
- 5.6 Each European Site is taken in turn and assessed with reference to the potentially adverse activity, first considering the site alone and then, if necessary, considering the site in-combination with other plans and projects.

### Testing for likely significant effects of the project alone

- 5.7 The screening of each European Site against each potentially adverse activity is set out below in a standard tabulated format (Tables 5, 6 and 7).

Table 5: Assessment of likely significant effects on the Montgomery Canal SAC

Site:	Interest features:
Montgomery Canal SAC	<ul style="list-style-type: none"> <li>• Annex II species that are a primary reason for selection of this site: Floating water-plantain <i>Luronium natans</i></li> </ul>
Potentially adverse activity:	Assessment:
Changes in air quality resulting in impacts on water quality through deposition – nitrogen deposition	<p>The Montgomery Canal SAC is described as ‘permanent oligotrophic water’ with a Critical Load (CL) for Nitrogen deposition of 3-10 kg N/ha/yr (<a href="http://www.apis.ac.uk">http://www.apis.ac.uk</a>, accessed 22 May 2020). Levels within the SAC are reported to be 12.2 kg N/ha/yr (average), with a range of 10.8 kg N/ha/yr (minimum) to 14.5 kg N/ha/yr (maximum), which indicates that the upper Critical Load for is already being exceeded for nitrogen (<a href="http://www.apis.ac.uk">http://www.apis.ac.uk</a>, accessed 22 May 2020).</p> <p>APIS (<a href="http://www.apis.ac.uk/">http://www.apis.ac.uk/</a>, accessed 22 May 2020) advises that the application of the CL for Nitrogen in any assessment should be subject to the following considerations:</p>

	<p><i>'Important Note: Seek site specific advice for site value. This critical load only applies if the interest feature is associated with softwater oligotrophic or dystrophic lakes at the site. If the feature is not depending on these lake types, there is no comparable critical load available. The critical load for C1.1 and C1.4<sup>3</sup> is 3-10 kgNha-1yr-1. The lower end of the range is intended for boreal and alpine lakes, and the higher end of the range for Atlantic softwaters. Site specific advice should be sought from the conservation agencies as to which part of the range is relevant. Note that the critical load should only be applied to oligotrophic waters with low alkalinity with no significant agricultural or other human inputs.'</i></p> <p>The conservation objectives for the component SSSI include an interim total phosphorus target for the whole canal of &lt;math&gt;40\mu\text{g L}^{-1}&lt;/math&gt; total phosphorus. No target is required for other elements, which suggests that P is considered to be the rate limiting nutrient. The interim total phosphorus target for the whole canal of &lt;math&gt;40\mu\text{g L}^{-1}&lt;/math&gt; suggests that it should be treated as being at the upper end of the mesotrophic<sup>4</sup> range (the proposed development will not be a significant source of phosphorus).</p> <p>Source attribution data (<a href="http://www.apis.ac.uk/">http://www.apis.ac.uk/</a>, accessed 22 May 2020) indicate that the current baseline exceedance is heavily influenced by agricultural sources. The APIS data (total Nitrogen deposition expressed as Kg N/ha/yr from sources by Region) indicate that the main sources are livestock 45.80% (Wales and England combined), road transport 8.91%, fertiliser 6.95% (Wales and England combined), shipping 5.28%, and European sources 14.35% (total 81.29%).</p> <p>Air quality modelling carried out by ECL<sup>5</sup> has calculated that the process contribution (PC) from the ERF will be 0.09 kg N/ha/yr, which is not significant in terms of the overall levels of nitrogen compared to the current levels. When the PC is compared to the CL for Nitrogen deposition it is equivalent to 2.96% of the lower CL and 0.89% of the upper CL. As noted above, the lower CL is intended for boreal and alpine lakes; the PC when compared to the upper CL falls below 1%<sup>6</sup> of the long-term environmental standard and so can be screened out.</p>
<p>Changes in air quality resulting in impacts on water quality through deposition – ammonia (NH<sub>3</sub>)</p>	<p>The Critical Level for ammonia is 3 (2-4) <math>\mu\text{g NH}_3/\text{m}^3</math> (annual mean). Site levels are reported to be 2.1 <math>\mu\text{g NH}_3/\text{m}^3</math> (average), ranging from 1.47 <math>\mu\text{g NH}_3/\text{m}^3</math> (minimum) to 2.64 <math>\mu\text{g NH}_3/\text{m}^3</math> (maximum), which is within the Critical Level range of 2-4 <math>\mu\text{g NH}_3/\text{m}^3</math> (this has been applied to reflect the sensitivities of different vegetation types). As noted above, source attribution data for nitrogen (which also considers NH<sub>3</sub> inputs) indicate that</p>

<sup>3</sup> C1.1 and C1.4 refers to the EUNIS ecosystem class. C1.1 is 'Permanent oligotrophic lakes, ponds and pools'; C1.4 is 'Permanent dystrophic lakes, ponds and pools'.

<sup>4</sup> OECD (1982) defines freshwater trophic categories as follows: oligotrophic = mean total P <math>10\mu\text{g l}^{-1}</math>; mesotrophic = mean total P 10-35  $\mu\text{g l}^{-1}</math>; eutrophic mean total P >35  $\mu\text{g l}^{-1}</math>$$

<sup>5</sup> Please see ECL Report ECL.001.01.02/ADMS which may be found as Technical Appendix 6-1 of the Environmental Statement submitted with the DNS Application.

<sup>6</sup> The Environment Agency has set a precautionary threshold of 1% of the Process Contribution (PC) below which the effects of aerial pollutants are considered to be insignificant (<https://www.gov.uk/guidance/air-emissions-risk-assessment-for-your-environmental-permit>).

	<p>agricultural, road transport, fertilizer and European sources collectively contribute 81.29%.</p> <p>Air quality modelling carried out by ECL<sup>7</sup> has calculated that the process contribution (PC) from the ERF will be 0.005 ug/m<sup>3</sup>, which is 0.03% of the Critical Level. This is not significant in terms of the overall levels of NH<sub>3</sub> (it is equivalent to 0.19% of the maximum level of 2.64 kg μg NH<sub>3</sub>/m<sup>3</sup> reported for the site).</p>
Changes in air quality resulting in impacts on water quality through deposition – Nitrogen Oxides (NOx)	<p>The Critical Level for nitrogen oxide is 30 μg NOx/m<sup>3</sup> (annual mean). Site levels are reported to be 10.78 μg NOx/m<sup>3</sup> (average), ranging from 4.75 μg NOx/m<sup>3</sup> (minimum) to 10.78 μg NOx/m<sup>3</sup> (maximum), which is well below the Critical Level. As noted above, source attribution data for nitrogen (which also considers NOx) indicate that agricultural, road transport, fertilizer and European sources collectively contribute 81.29%.</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be 0.062 ug/m<sup>3</sup>, which is 0.21% of the Critical Level. This is not significant in terms of the overall levels of NOx as levels will still fall well below the Critical Level.</p>
Changes in air quality resulting in impacts on water quality through deposition – Sulphur Dioxide (SO <sub>2</sub> )	<p>The Critical Level for sulphur dioxide is 10-20 μg SO<sub>2</sub>/m<sup>3</sup> (annual mean). Site levels are reported to be 0.88 μg SO<sub>2</sub>/m<sup>3</sup> (average), ranging from 0.74 μg SO<sub>2</sub>/m<sup>3</sup> (minimum) to 1.58 μg SO<sub>2</sub>/m<sup>3</sup> (maximum), which is well below the Critical Level.</p> <p>Source attribution data indicate that most SO<sub>2</sub> is derived from existing industrial sources and shipping (more than 72%).</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be 0.026 ug/m<sup>3</sup>, which is 0.13% of the Critical Level. This is not significant in terms of the overall levels of SO<sub>2</sub>, as levels will still fall well below the Critical Level.</p>
Conclusion	<p>No likely significant effect arising from changes in N-deposition, ammonia, NOx and SO<sub>2</sub>.</p>
Overall conclusion	<p>The proposed development alone will not have a likely significant effect on this European Site and its interest features and no reasonable scientific doubt remains in reaching this conclusion. In light of this it is necessary to carry out an 'in combination' assessment to ascertain whether the project will have a likely significant effect in combination with other projects (see Section 6).</p>

<sup>7</sup> Please see ECL Report ECL.001.01.02/ADMS which may be found as Technical Appendix 6-1 of the Environmental Statement submitted with the DNS Application.

Table 6: Assessment of likely significant effects on the Granllyn SAC

Site:	Interest features:
Granllyn SAC	<ul style="list-style-type: none"> <li>Annex II species that are a primary reason for selection of this site: great crested newt <i>Triturus cristatus</i></li> </ul>
Potentially adverse activity:	Assessment:
Changes in air quality resulting in impacts on water quality through deposition – N-deposition	<p>The Granllyn SAC is described as ‘standing open water’ where no Empirical Critical Load value is available for the supporting habitat or for the species (<a href="http://www.apis.ac.uk">http://www.apis.ac.uk</a>, accessed 18 September 2019). Site levels for Nitrogen deposition are reported by APIS to be 12.2 kg N/ha/yr.</p> <p>Source attribution data indicate that 29% of nitrogen is derived locally from Welsh livestock sources, with a further 18% derived from English livestock sources. Further contributions come from international shipping (6%), road transport (5%), fertiliser (3%), and a 16% contribution comes from European sources. In summary, current nitrogen levels are primarily due to agricultural and transport related sources which collectively contribute 77% of nitrogen deposition.</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be 0.0048 kg N/ha/yr, which is not significant in terms of the overall levels of nitrogen compared to the current levels (the PC is less than 0.04% of current baseline levels).</p>
Changes in air quality resulting in impacts on water quality through deposition – ammonia (NH <sub>3</sub> )	<p>The Critical Level for ammonia is 3 (2-4) µg NH<sub>3</sub>/m<sup>3</sup> (annual mean). Site levels are reported to be 2.05 µg NH<sub>3</sub>/m<sup>3</sup>, which is just within the Critical Level range of 2-4 µg NH<sub>3</sub>/m<sup>3</sup> (this has been applied to reflect the sensitivities of different vegetation types). As noted above, source attribution data for nitrogen (which also considers NH<sub>3</sub> inputs) indicate that agricultural and transport related sources collectively contribute 77%.</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be 0.002 ug/m<sup>3</sup>, which is 0.01% of the Critical Level. This is not significant in terms of the overall levels of NH<sub>3</sub> (it is equivalent less than 0.1% of the maximum level of 2.26 kg µg NH<sub>3</sub>/m<sup>3</sup> reported for the site).</p>
Changes in air quality resulting in impacts on water quality through deposition – Nitrogen Oxides (NO <sub>x</sub> )	<p>The Critical Level for nitrogen oxides is 30 µg NO<sub>x</sub>/m<sup>3</sup> (annual mean). Site levels are reported to be 5.09 µg NO<sub>x</sub>/m<sup>3</sup>, which is well below the Critical Level. As noted above, source attribution data for nitrogen (which also considers NO<sub>x</sub>) indicate that agricultural and transport related sources collectively contribute 77%.</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be 0.019 NO<sub>x</sub> ug/m<sup>3</sup>, which is 0.06% of the Critical Level. This is not significant in terms of the overall levels of NO<sub>x</sub> as levels will still fall well below the Critical Level.</p>

<p>Changes in air quality resulting in impacts on water quality through deposition – Sulphur Dioxide (SO<sub>2</sub>)</p>	<p>The Critical Level for sulphur dioxide is 10-20 µg SO<sub>2</sub>/m<sup>3</sup> (annual mean). Site levels are reported to be 0.94 µg SO<sub>2</sub>/m<sup>3</sup>, which is well below the Critical Level.</p> <p>Source attribution data indicate that most SO<sub>2</sub> is derived from existing industrial sources, European sources and shipping (more than 73%).</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be 0.008 ug/m<sup>3</sup>, which is 0.04% of the Critical Level. This is not significant in terms of the overall levels of SO<sub>2</sub>, as levels will still fall well below the Critical Level.</p>
<p>Conclusion</p>	<p>No likely significant effect arising from changes in N-deposition, ammonia, NOx and SO<sub>2</sub>.</p>
<p>Overall conclusion</p>	<p>The development of the Site alone will not have a likely significant effect on this European Site and its interest features and no reasonable scientific doubt remains in reaching this conclusion. In light of this it is necessary to carry out an ‘in combination’ assessment to ascertain whether the project will have a likely significant effect in combination with other projects (see Section 6).</p>

Table 7: Assessment of likely significant effects on the Midland Meres and Mosses – Phase 1 Ramsar site

<p><b>Site:</b></p>	<p><b>Interest features:</b></p>
<p>Midland Meres and Mosses – Phase 1 Ramsar site</p>	<ul style="list-style-type: none"> <li>• The site comprises a diverse range of habitats from open water to raised bog.</li> <li>• The site supports a number of rare species of plants associated with wetlands including five nationally scarce species.</li> <li>• The site supports an assemblage of rare wetland invertebrates.</li> </ul>

Potentially adverse activity:	Assessment:
<p>Changes in air quality resulting in impacts on water quality through deposition – N-deposition</p>	<p>No air quality data are available for the Ramsar site; however, data are available for Marton Pool, Chirbury SSSI, which is a component SSSI of the SAC that is located within 10 km of the Site (all other component SSSIs are located more than 10 km from the Site). Empirical Critical Load values for Nitrogen deposition are provided by APIS for:</p> <ul style="list-style-type: none"> <li>• Broad-leaved, mixed and yew woodland (<i>Alnus glutinosa</i> - <i>Urtica dioica</i> woodland) – 10-20 kg N/ha/yr;</li> <li>• Fen, marsh and swamp (<i>Phragmites australis</i> swamp and reed-beds) – 15-30 kg N/ha/yr;</li> <li>• Fen, marsh and swamp (<i>Scirpus lacustris</i> ssp. <i>lacustris</i> swamp) – habitat is not sensitive to nitrogen;</li> <li>• Fen, marsh and swamp (<i>Typha angustifolia</i> swamp) – habitat is not sensitive to nitrogen.</li> </ul> <p>(source: <a href="http://www.apis.ac.uk">http://www.apis.ac.uk</a>, accessed 22 May 2020).</p> <p>Published data (source: <a href="http://www.apis.ac.uk">http://www.apis.ac.uk</a>, accessed 22 May 2020) indicate that the current nitrogen level in the woodland is 32.9 kg N/ha/yr, which indicates that the Critical Load for this habitat is currently exceeded (in the absence of development).</p> <p>Published data also indicate that the current nitrogen level in the fen, marsh and swamp habitat is 19.5 kg N/ha/yr, which is at the lower end of the Critical Load range for this habitat.</p> <p>Source attribution data (source: <a href="http://www.apis.ac.uk">http://www.apis.ac.uk</a>, accessed 22 May 2020) indicate that 31% of nitrogen is derived locally from English livestock sources, with a further 18% derived from Welsh livestock sources. Further contributions come from fertiliser inputs (6%), and a 15% contribution comes from European sources. In summary, current nitrogen levels are primarily due to agricultural and European sources which collectively contribute 70% of nitrogen deposition.</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be 0.086 kg N/ha/yr (total nitrogen), which is not significant in terms of the overall levels of nitrogen compared to the current levels. The PC is equivalent to 0.86% of the lower critical load and 0.43% of the upper critical load for 'Broad-leaved, mixed and yew woodland'. The PC is also equivalent to 0.57% of the lower critical load and 0.29% of the upper critical load for 'Fen, marsh and swamp'. The PC therefore falls below 1%<sup>8</sup> of the long-term environmental standard and so can be screened out.</p>

<sup>8</sup> The Environment Agency has set a precautionary threshold of 1% of the Process Contribution (PC) below which the effects of aerial pollutants are considered to be not significant (<https://www.gov.uk/guidance/air-emissions-risk-assessment-for-your-environmental-permit>).

<p>Changes in air quality resulting in impacts on water quality through deposition – ammonia (NH<sub>3</sub>)</p>	<p>The Critical Level for ammonia is 3 (2-4) µg NH<sub>3</sub>/m<sup>3</sup> (annual mean). Current site levels (in the absence of development) are reported to be 2.23 µg NH<sub>3</sub>/m<sup>3</sup>, which is just within the range of 2-4 µg NH<sub>3</sub>/m<sup>3</sup> (that has been applied to reflect the sensitivities of different vegetation types). As noted above, source attribution data for nitrogen (which also considers NH<sub>3</sub> inputs) indicate that agricultural and European sources collectively contribute 70%.</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be 9.29E-05 ug/m<sup>3</sup>, which is 0.01% of the Critical Level. This is not significant in terms of the overall levels of NH<sub>3</sub> (it is equivalent to less than 0.1% of the maximum level of 2.23 kg µg NH<sub>3</sub>/m<sup>3</sup> reported for the site and falls below 1% of the long-term environmental standard and so can be screened out).</p>
<p>Changes in air quality resulting in impacts on water quality through deposition – Nitrogen Oxide (NO<sub>x</sub>)</p>	<p>The Critical Level for nitrogen oxide is 30 µg NO<sub>x</sub>/m<sup>3</sup> (annual mean). Current site levels are reported to be 4.39 µg NO<sub>x</sub>/m<sup>3</sup>, which is well below the Critical Level. As noted above, source attribution data for nitrogen (which also considers NO<sub>x</sub>) indicate that agricultural and European sources collectively contribute 70%.</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be less than 0.1% of the Critical Level. This is not significant in terms of the overall levels of NO<sub>x</sub>, i.e. it falls below 1% of the long-term environmental standard and so can be screened out.</p>
<p>Changes in air quality resulting in impacts on water quality through deposition – Sulphur Dioxide (SO<sub>2</sub>)</p>	<p>The Critical Level for sulphur dioxide is 10-20 µg SO<sub>2</sub>/m<sup>3</sup> (annual mean) for all vegetation. Current site levels are reported to be 0.78 µg µg SO<sub>2</sub>/m<sup>3</sup>, which is well below the Critical Level.</p> <p>Source attribution data indicate that most SO<sub>2</sub> is derived from existing industrial sources, shipping and European sources (more than 76%).</p> <p>Air quality modelling carried out by ECL has calculated that the process contribution (PC) from the ERF will be in the region of 0.1% of the Critical Level (lower limit). This is not significant in terms of the overall levels of SO<sub>2</sub>, i.e. it falls below 1% of the long-term environmental standard and so can be screened out.</p>
<p>Conclusion</p>	<p><b>No likely significant effect arising from changes on N-deposition, ammonia, NO<sub>x</sub> and SO<sub>2</sub>.</b></p>
<p>Overall conclusion</p>	<p>The development of the Site alone will not have a likely significant effect on this European Site and its interest features and no reasonable scientific doubt remains in reaching this conclusion. In light of this it is necessary to carry out an 'in combination' assessment to ascertain whether the project will have a likely significant effect in combination with other projects.</p>

**Summary of Likely Significant Effects**

5.1 The assessment of the project alone has concluded that the proposed ERF plant is not likely to have a significant effect on the following European sites (Figure 2, Section 9):

- Montgomery Canal SAC;
- Granllyn SAC; and

- Midland Meres and Mosses – Phase 1 Ramsar site.

5.2 Whilst the proposed development will result in the generation of aerial pollutants, modelling shows that these will be at very low levels compared to the current baseline conditions. Agriculture is currently the main contributor to elevated levels of nitrogen deposition, ammonia and NO<sub>x</sub>. Industrial sources and shipping are the main contributors of SO<sub>2</sub>.

## 6 In-Combination Assessment

- 6.1 There is a requirement under Regulation 63(1)a to complete an assessment of whether a plan or project, either alone or in combination with other plans or projects, is likely to have a significant effect on any European Sites' qualifying features (habitats and species) and the achievement of the European Site's conservation objectives. An assessment has been completed of the development alone, but a further assessment is therefore required of the Development in combination with other plans and projects.
- 6.2 In the absence of a searchable map facility on the Powys County Council planning portal, the following approach has been adopted for the in-combination assessment:
- The Defra MAGIC database was used to identify Community boundaries within 10 km of the Site;
  - Ordnance Survey maps were used to identify likely centres of industrial activity and this was cross-checked against the Powys Local Plan Proposals Maps, the Powys Local Development Plan 2011 – 2026 Written Statement, and the C39 Economic Development Strategy Appendix D;
  - The Welshpool Community area was identified as being a potential location of applications for industrial processes that could result in an 'in-combination' effect with the ERF (all other Community areas comprise small scattered developments where significant aerial pollution sources are unlikely);
  - The monthly planning lists were interrogated using the Powys County Council planning portal to identify industrial processes that need to be considered in the 'in-combination' assessment (monthly lists were available for the period July 2019 to May 2020).
- 6.3 No additional plans or projects have been identified that need to be considered as part of the in-combination assessment.

## 7 Conclusion

- 7.1 It is concluded that the development is not likely to have a significant effect on the qualifying features of the Montgomery Canal SAC, Granllyn SAC and Midland Meres and Mosses – Phase 1 Ramsar site as a result of changes in air quality that are predicted to arise during the operation of the Site.
- 7.2 There are not likely to be significant effects on the Montgomery Canal SAC, Granllyn SAC and Midland Meres and Mosses – Phase 1 Ramsar site or their qualifying features (including functionally linked land) because of the separation distance between the Development and the designated sites. The Development will result in a small increase in aerial pollutants during the operation phase; however, the predicted Process Contribution is small when compared to the relevant Critical Load or Critical Level. Baseline air quality levels are elevated in the absence of the development, with this being attributed to agricultural sources, road traffic, shipping, European sources and industrial sources.
- 7.3 This conclusion has been reached in the absence of mitigation and is therefore compliant with CJEU judgment C-323/17. No reasonable scientific doubt remains in reaching this conclusion.
